

# Xylazine Wound Care Protocol for Harm Reduction and Street Outreach Settings

*Presenter: Kristin E. Schneider, PhD  
Johns Hopkins Bloomberg School of Public Health*

Co-Authors: Suzanne J. Block, Jason Bienert, Susan G. Sherman, Danielle Friedman  
Nestadt

# Goal

To provide useful practical guidance for xylazine wound care in street medicine/outreach settings

# Protocol Development

- ▶ 16 interviews with clinical providers of wound care for PWUD
- ▶ Review of medical and harm reduction literature
- ▶ Synthesized real-world clinical experience from providers with existing nursing frameworks to create a protocol to guide xylazine wound care planning

# Who can provide wound care?

- ▶ Medical training isn't necessary for many aspects of wound care
- ▶ Depends on individual willingness/comfort
- ▶ Organizational liability concerns and comfort

# ABCDE Framework (Harm Reduction-ified)

**A**

Assess patient wound and wellbeing

**B**

Bring in multidisciplinary services to promote holistic care

**C**

Address underlying causes and barriers to wound healing

**D**

Decide appropriate treatment

**E**

Evaluate and Empower

# Identifying Xylazine Wounds

- ▶ Drug use history suggestive of xylazine use
- ▶ Wound appeared away from the injection site, typically on extremities
- ▶ Wounds typically start small and expand quickly
- ▶ Appearance:
  - ▶ Blister-like with a dark layer under skin
  - ▶ Red or purple skin discoloration
  - ▶ Hard, dry tissue
  - ▶ Black, dead, or necrotic tissue not due to infection

# When is higher level care needed?

- ▶ **Signs of systemic infection** (e.g., sepsis, osteomyelitis)
  - ▶ Fever
  - ▶ Chills/Shivering
  - ▶ Nausea
  - ▶ Vomiting
  - ▶ Diarrhea
  - ▶ Increased heart rate (over 100 beats per minute)
  - ▶ Increased respiratory rate (over 20 breaths per minute)
  - ▶ Low blood pressure (under 90/60 mmHg)
  - ▶ Poor blood flow (pale, capillary refill < 3 seconds)
  - ▶ Altered mental status (confusion, sleepy)
- ▶ **Exposed tendon, bone, or other underlying structure**
- ▶ **Wound located on/near area with highly complicated underlying structures** (e.g., near eyes, arteries)
- ▶ **Weakness or impaired motor function** indicative of nerve damage or infective arthritis

# Assessing a Wound Using TIME

T

Tissue - Is the tissue viable?

I

Infection/Inflammation - Does the wound appear infected or inflamed?

M

Moisture Balance - Is the wound bed dry or moist?

E

Edges - Does the wound edge appear to be abnormal or advancing?

# Cleansing and Debridement

- ▶ Remove dead tissue to help healing and decrease infection risk
- ▶ Cleansing with soap and water/saline is usually sufficient
- ▶ Gentle mechanical debridement is usually warranted
- ▶ Autolytic debridement using Medihoney is another common approach
- ▶ Sharp/surgical debridement should only be done by healthcare providers

# Dressing

The outer layer makes sure the dressing stays in place and protects from dirt and moisture

The absorbent layer absorbs drainage (abd pad, sponge, or gauze )

The contact layer touches the wound (xeroform, honey gauze, Telfa pad, A&D ointment, drawing salve)

# Critical Role of Client Education

- ▶ Clients should be considered partners in their wound care
- ▶ Provide education and supplies to empower the patient to independently care for their wound
  - ▶ Tailor to client's unique needs
  - ▶ Explain what you're doing as you go
  - ▶ Use the teach-back method or have patients perform wound care under your direction
  - ▶ Provide educational material, when appropriate or requested
